THE AI LENDER MATCH · DATA REQUIREMENTS · 4 AUGUST 2026

“Type the case, get the lender” — what it needs

You described it exactly: a simple narration in a text box (later a voice note) that throws the best possible lender, based on the product library and past data. It is buildable, in three levels — each one usable on its own, each unlocked by a specific piece of data. This page says precisely what to send for each. The attached Excel (template v2) has a sheet for every item.

1 Narration box → best lender

NO NEW DATA NEEDED

Someone types: *“LAP, self-employed manufacturer in Surat, needs 2 Cr against industrial property worth 5 Cr, CIBIL around 720”* — the system reads product, amount, property, profile, location and CIBIL out of the sentence and runs the Best Match engine that is already live. Ranked lenders, with reasons, from plain text.

Needs: nothing beyond the programme library you’re already filling. The voice-note version is this plus speech-to-text on top — same engine.

2 Rankings that reflect your commercials

NEEDS: PAYOUT + CITY TIERS

For the ranking to prefer what genuinely pays QCred best — and to apply the right loan ceilings by location — it needs the two things you named tonight:

Data	Sheet in template v2	Notes
Payout per lender × product	`Payout Grid`	One row per combination, with bonus slabs. Since these change monthly with targets, send an updated sheet any time — it reloads in minutes.
City tiers per lender	`City Tiers (per lender)`	Each lender’s own classification, one row per lender + city. Once loaded, entering the customer’s city applies that lender’s tier limits automatically.

3 The learning model — “based on past data”

NEEDS: FILE HISTORY

This is where it becomes AI in the real sense: the model learns which lender actually says yes — per product, profile, geography and ticket size — and starts predicting approval likelihood, not just eligibility. For that it needs your **past files with outcomes**:

Per past file	Why it matters
Product · lender submitted to · amount · city	What the case was and where it went
Profile (Salaried / SEP / SENP) · CIBIL band · property type	What the lender was judging
Outcome — Approved / Rejected / Disbursed / Withdrawn, + rejection reason	The thing the model learns from
Days to decision · disbursed amount	Lets it also rank by speed and slippage

No customer names or numbers needed — the model learns lender behaviour, not identities. 6–12 months of files is ideal; even 200–300 rows gives a useful first model, and it improves continuously because **every file processed in the CRM from now on records these outcomes automatically**. The history you provide is the head start.

The practical sequence

Send the **Payout Grid** and **City Tiers** sheets as the data exists — each loads within a day of arriving. The **Past Files** sheet can come in parts, whenever your MIS can export it. Level 1 (the narration box) we can build meanwhile, since it needs nothing new — and Levels 2 and 3 switch on underneath it as the data lands, without changing how anyone uses it.
